

- 1) Define a structure in C & CPP.
This structure should hold the variables for student type. Compute the size of structure manually.
- 2) Use size of function & display the size.
Cross check if both are same or not justify.

C++
#include <iostream>
using namespace std;

```
struct student {
    int id;
    char name[20];
    float marks;
};
```

```
int main() {
    student s;
    cout << "Size using variable = " << size of (s) << endl;
    cout << "Size using using structure = " << size of (student) << endl;
```

```
    if (size of (s) == size of (student))
        cout << "Both are same";
    else
        cout << "Both are different";
    return 0;
}
```
